

# Magnitude 6.3 - Central Italy

Wed Apr 8 19:00:01 UTC 2009

10 earthquakes on this map

- > at least 227 killed
- > 1000 injured, 10000 bldgs destroyed or damaged
- > occurred in central Appenines, a mountain range formed as a large accretionary wedge
- > Mediterranean highly complex due to interactions of numerous microplates

#### Earthquake Details

<b>Magnitude</b>	<b>6.3</b>
<b>Date-Time</b>	<b>Monday, April 06, 2009 at 01:32:39 UTC</b> Monday, April 06, 2009 at 03:32:39 AM at epicenter <a href="#">Time of Earthquake in other Time Zones</a>
<b>Location</b>	42.334°N, 13.334°E
<b>Depth</b>	8.8 km (5.5 miles) set by location program
<b>Region</b>	CENTRAL ITALY
<b>Distances</b>	75 km (45 miles) W of <b>Pescara, Italy</b> 85 km (55 miles) NE of <b>ROME, Italy</b> 115 km (75 miles) SE of <b>Perugia, Italy</b> 145 km (90 miles) S of <b>Ancona, Italy</b>
<b>Location Uncertainty</b>	Error estimate not available
<b>Parameters</b>	NST=321, Nph=321, Dmin=6 km, Rmss=0 sec, Gp= 14°, M-type=teleseismic moment magnitude (Mw), Version=A
<b>Source</b>	Istituto Nazionale di Geofisica e Vulcanologia, Rome, Italy
<b>Event ID</b>	us2009fcaf

This event has been reviewed by a seismologist.

[Did you feel it?](#) Report shaking and damage at your location. You can also view a map displaying accumulated data from your report and others.

# EARTHQUAKE SIZE

How do we measure the size of an earthquake?

What other factors influence amplitude of signals on seismograms?

# DEVELOPMENT OF MAGNITUDE SCALE

> expect signal amplitude to vary with distance to epicenter

> seismologists K Wadati and C Richter both noticed that peak ground motion of quakes varied with distance

> proposed magnitude scale through analogy with stellar brightness scale (similar to pH scale)

# CONCEPT OF MAGNITUDE

> first measure of size was termed “magnitude”

> magnitude scales have form:

$$M = \log(A/T) + F(h, \Delta) + C$$

$A$  : signal amplitude

$T$  : dominant period

$F(h, \Delta)$  : correction for quake depth & distance

$C$  : regional scale factor

> logarithmic: unit increase equivalent to 10-fold increase in signal amplitude; necessary since earth motions span a range of  $10^{10}$

# HISTORY OF MAGNITUDES

> first devised by Charles Richter in 1935 for S California: ``Richter Scale'' or ``local'' magnitude

$$M_L = \log A + 2.76 \log \Delta - 2.48$$

> valid for Wood-Anderson seismograph (resonant frequency = 0.8 Hz) and uses S-wave amplitude

> sometimes still reported since good indicator of structural damage

> later modifications include global body wave and surface wave scales:

$$m_b = \log(A/T) + Q(h, \Delta) \quad M_s = \log(A/T) + 1.6 \log \Delta + 3.3$$

# RICHTER SCALE FOR LOCAL MAGNITUDE

> magnitude found from amplitude of largest arrival and the S-P travel time difference

> in example, maximum amplitude is 23mm and S-P time is 24 s, yielding an ML of 5.0

# MAGNITUDES AS MEASURES OF EARTHQUAKE SIZE

## ***ADVANTAGES:***

1. directly measured from seismograms; no sophisticated signal processing required
2. yield units of order 1, providing intuitively attractive scale: M=5, moderate; M=6, strong, M=7, major, M=8, great etc.

## ***LIMITATIONS:***

1. entirely empirical, not physically based (dimensions don't match)
2. magnitudes often discrepant between scales
3. magnitude scales saturate

# MAGNITUDE DISCREPANCIES

Earthquake	Body wave magnitude $m_b$	Surface wave magnitude $M_s$	Fault area ( $\text{km}^2$ ) length $\times$ width	Average dislocation (m)	Moment (dyn-cm) $M_0$	Moment magnitude $M_w$
Truckee, 1966	5.4	5.9	$10 \times 10$	0.3	$8.3 \times 10^{24}$	5.8
San Fernando, 1971	6.2	6.6	$20 \times 14$	1.4	$1.2 \times 10^{26}$	6.7
Loma Prieta, 1989	6.2	7.1	$40 \times 15$	1.7	$3.0 \times 10^{26}$	6.9
San Francisco, 1906		8.2	$320 \times 15$	4	$6.0 \times 10^{27}$	7.8
Alaska, 1964	6.2	8.4	$500 \times 300$	7	$5.2 \times 10^{29}$	9.1
Chile, 1960		8.3	$800 \times 200$	21	$2.4 \times 10^{30}$	9.5

> note discrepant body-wave and surface wave magnitudes (due to empirical nature, no account for radiation pattern, fault dimensions and locations can vary along fault etc).

> body-wave magnitudes saturate at  $\sim 6.2$ , surface wave magnitudes at  $\sim 8.4$

# THE SEISMIC MOMENT

> a physically based measure of earthquake size/energy (units?)

$$M_0 = \mu D S$$

$\mu$  : rigidity (shear modulus) of fault materials

$D$  : slip as function of time

$S$  : fault area

> latter terms are time-dependent since they can vary during an earthquake but we approximate as constant

# RELATIVE AREAS, SLIP MOMENTS OF SOME EARTHQUAKES

# THE MOMENT MAGNITUDE

> moment estimated through sophisticated modelling of seismograms to estimate  $D, S$

> define moment magnitude as:

$$M_w = \frac{\log M_0}{1.5} - 10.73$$

> physically based with terms 1.5, 10.73 chosen to achieve good agreement with  $m_b, M_s$

> doesn't saturate

> largest earthquakes bounded to  $M_w < 10$

# ENERGY RELEASE

> seismic moment and moment magnitude allow us to compare size of largest earthquakes

> find that energy release for earthquakes of last century is dominated by a few large subduction earthquakes
