

# EARTHQUAKE LOCATIONS

1. modern, high precision locations using double difference methods

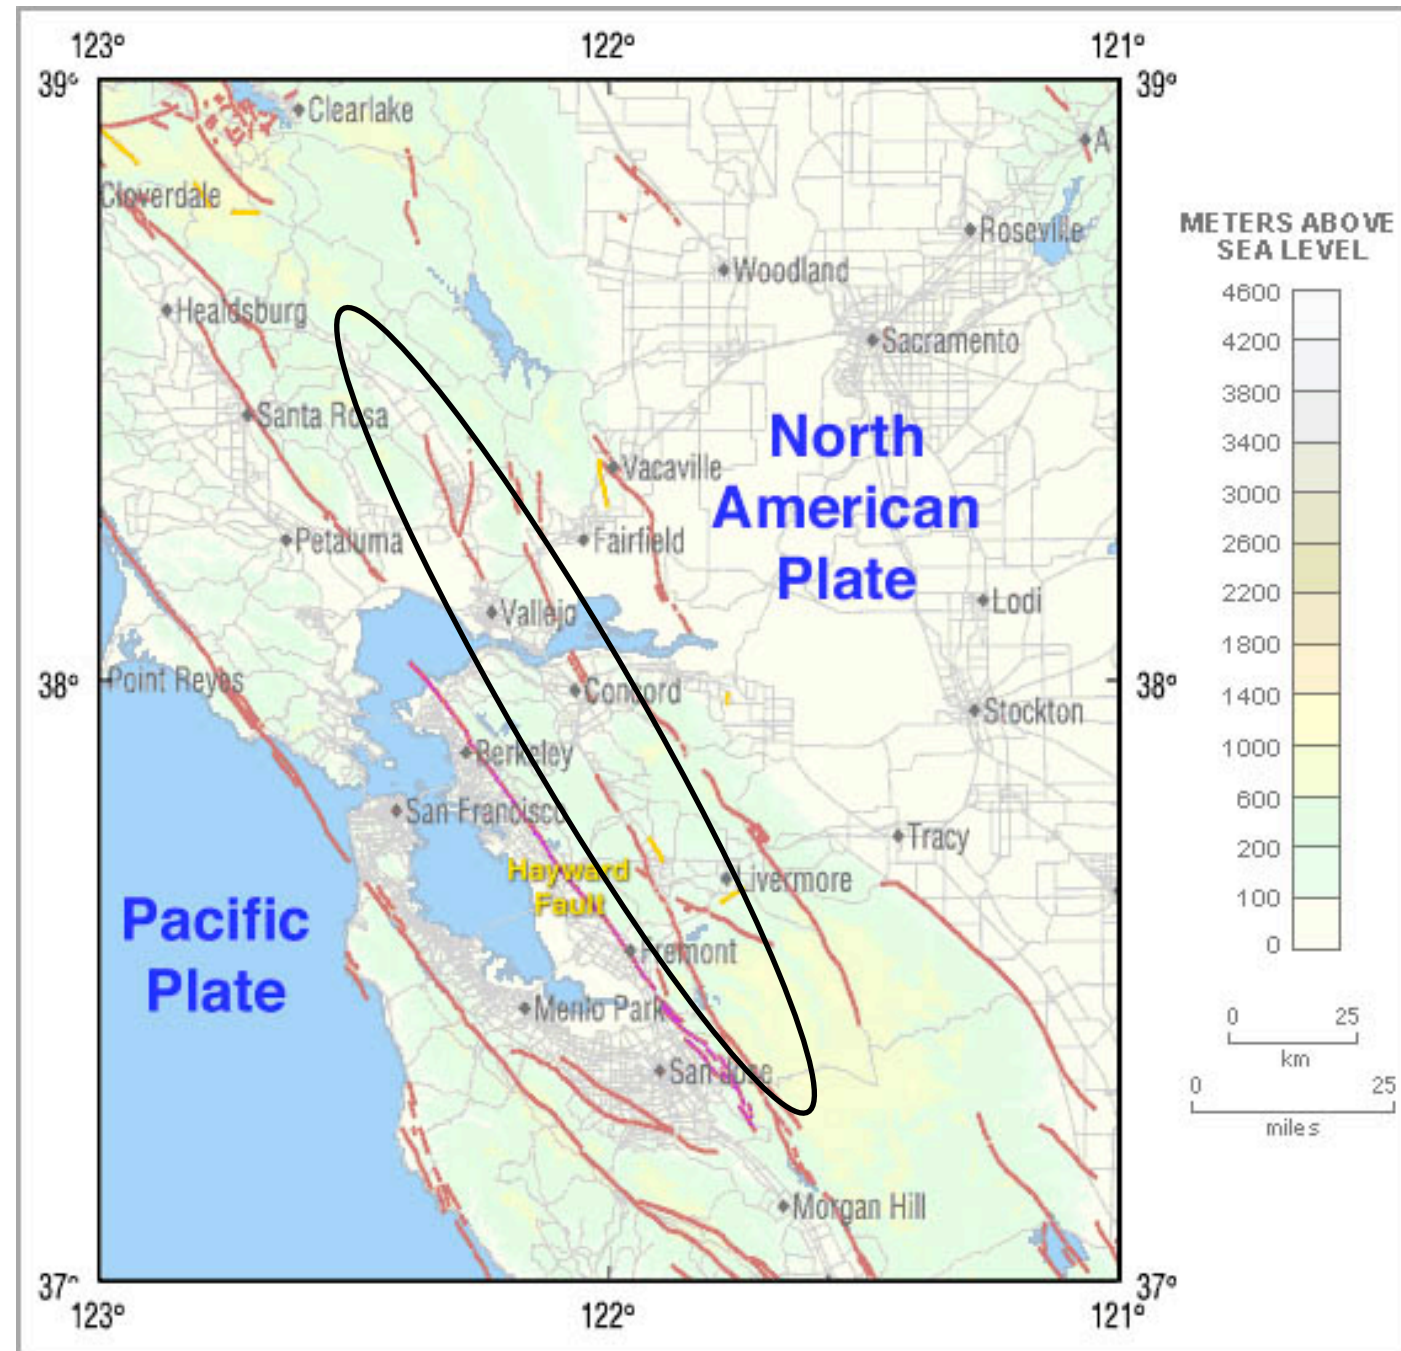

2. hypocenters in Cascadia

3. Wadati-Benioff Seismicity

4. hypocenters in other parts of western Canada

# CALVERAS FAULT SYSTEM

> major branch  
of San Andreas

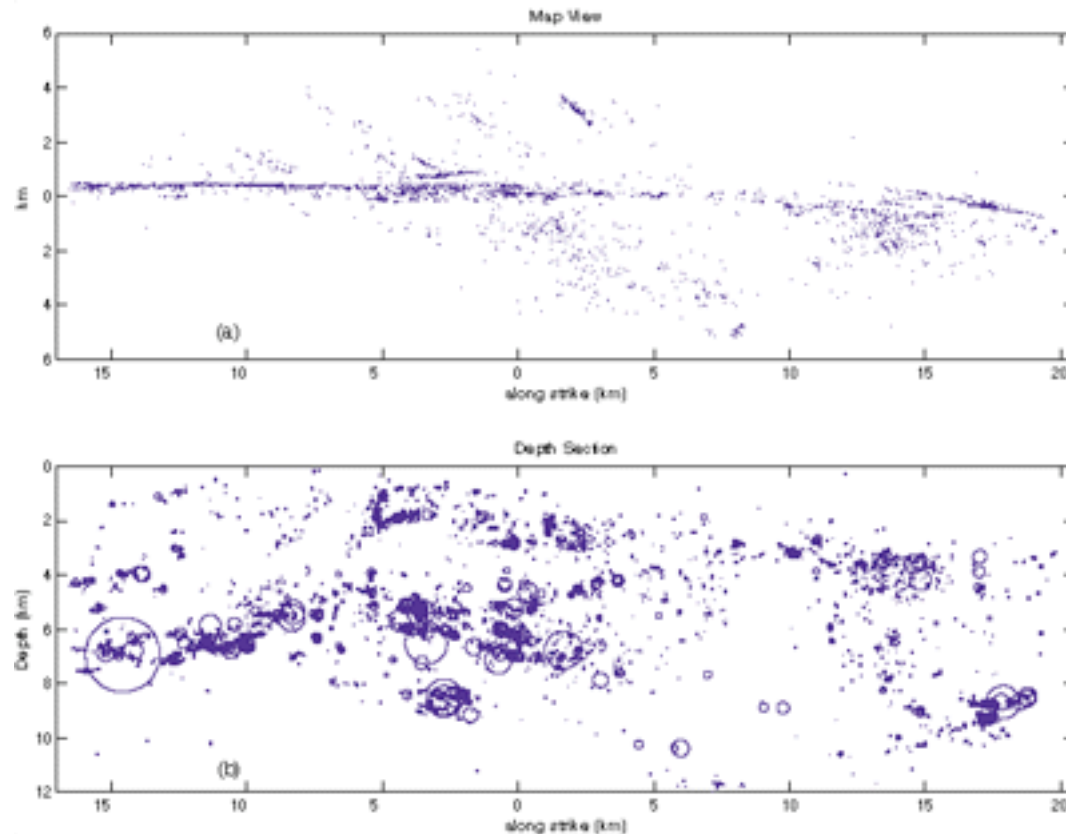

# EARTHQUAKE LOCATIONS ON THE CALVERAS FAULT - CALIFORNIA

- > earthquake locations using conventional methods
- > note epicenters in map view define linear fault trace (7757 quakes from 1984 to present)
- > size of circle scales with magnitude of earthquake

# IMPROVED LOCATIONS USING DOUBLE-DIFFERENCE APPROACH

- > double difference method employs relative timing variations between different earthquakes (only possible where dense station/eq coverage)
- > note improved resolution especially in vertical direction
- > new definition of several off-fault structures, and restriction of seismicity to well-defined bands

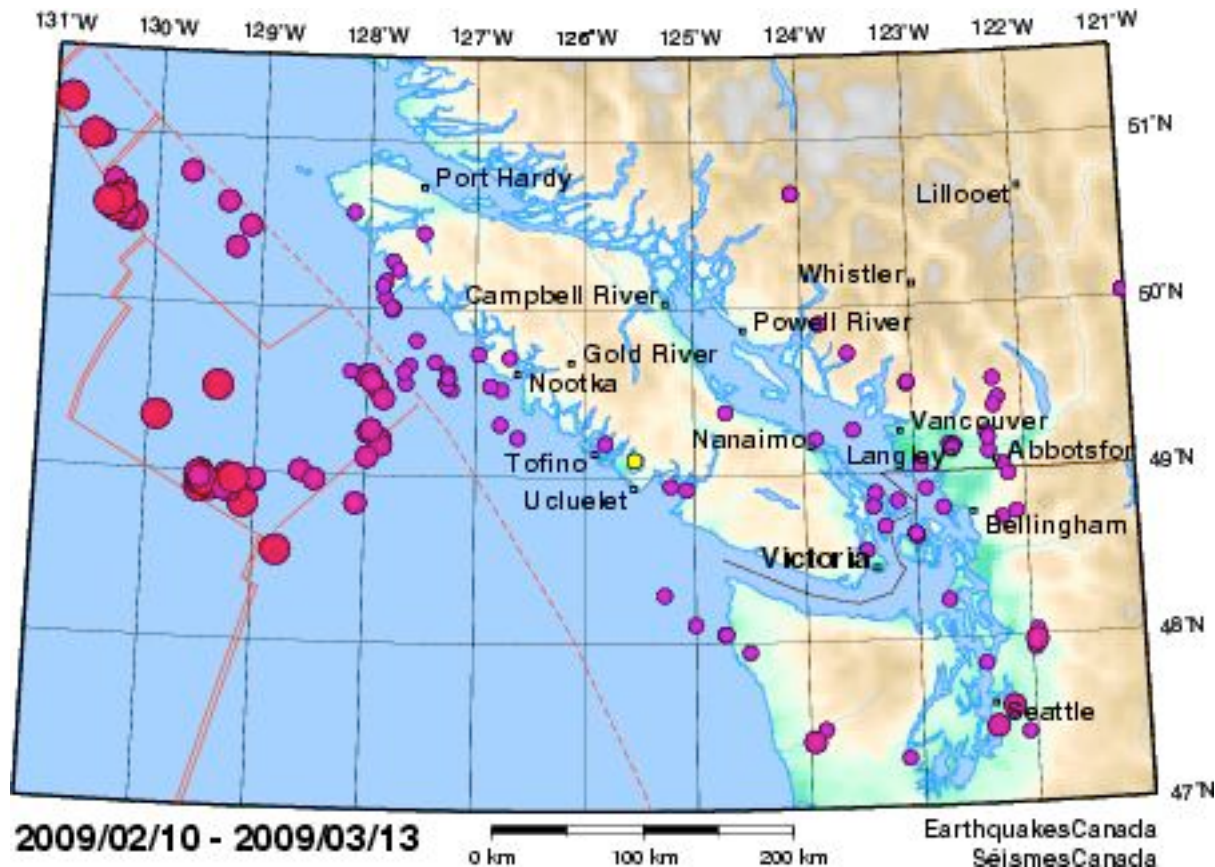

# EARTHQUAKE LOCATIONS ON TRANSFORM FAULTS AND RIDGES

- > note earthquake hypocenters on transform faults generally above 15 km which is depth to brittle ductile transition
- > at mid-ocean ridges hypocenters are still shallower  $\sim < 5$  km

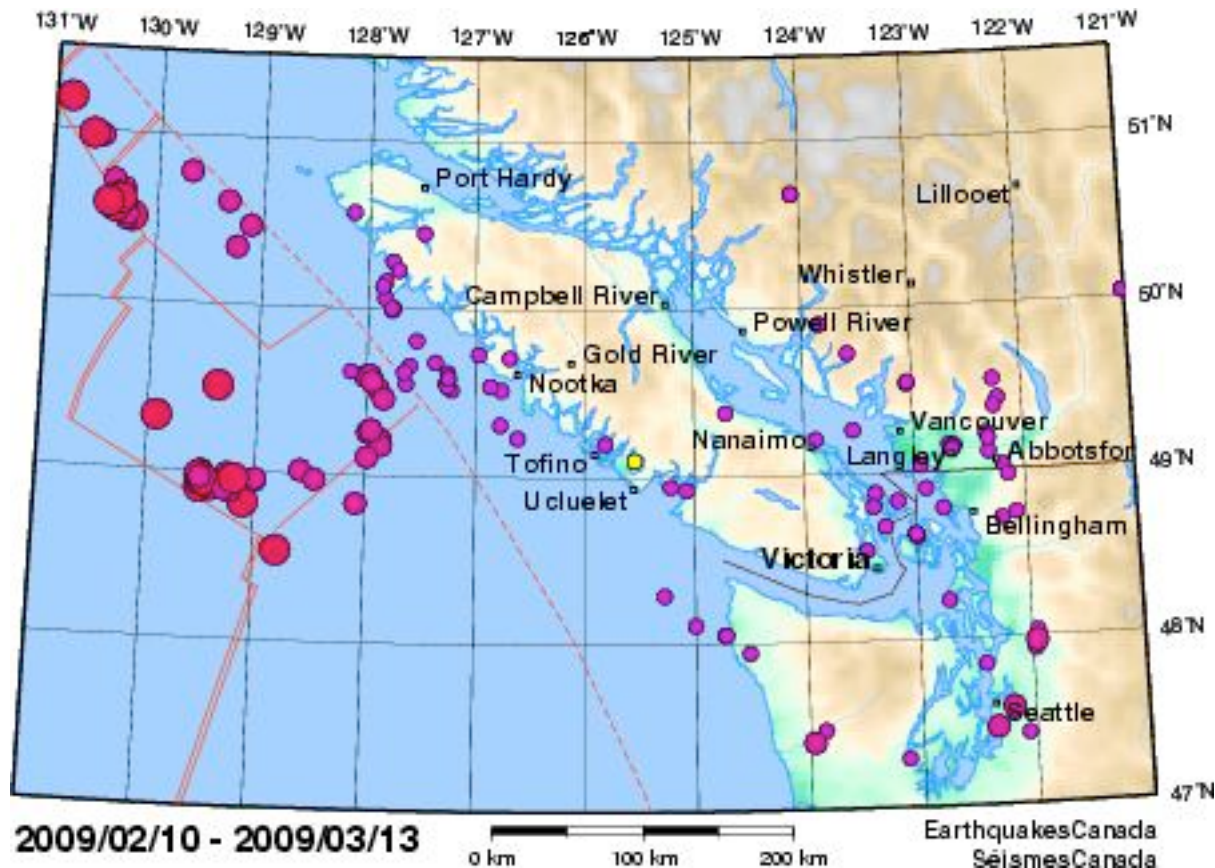

# EARTHQUAKE LOCATIONS IN BC

- > offshore earthquakes poorly located - why?
- > epicenters on NA plate are either in continental crust or in down-going plate - NOT on boundary!

# EARTHQUAKE LOCATIONS IN BC

- > earthquake locations are most accurately determined if epicenter lies within network
- > for this reason, depths are usually less well determined than epicenters

# EARTHQUAKES IN CASCADIA

A: intracrustal (e.g. Vancouver I, June 23, 1946,  $M=7.3$ )

B: intraplate (or Wadati-Benioff, e.g. Seattle February 28, 2001,  $M=6.8$ )

C: megathrust (e.g. January 26, 1700,  $M=9.?$ )

D: episodic tremor and slip (every 14 months)

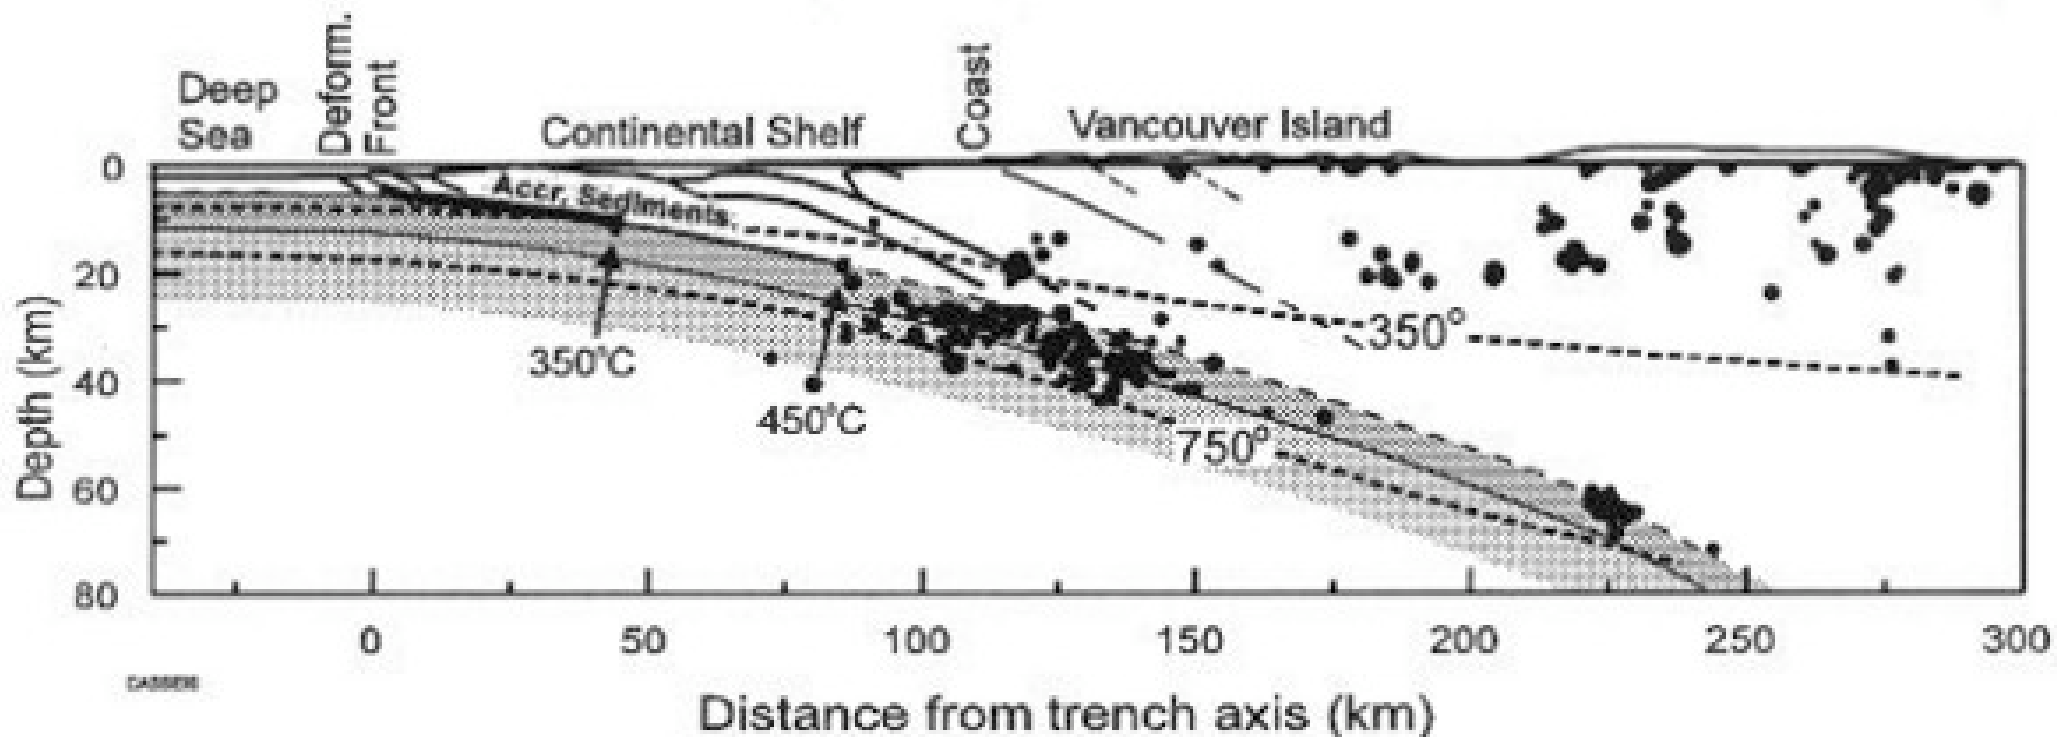

# CASCADIA HYPOCENTERS

- > deepest hypocenters represent intraplate earthquakes
- > in Cascadia, no deeper than ~80 km - WHY?

# CASCADIA HYPOCENTERS

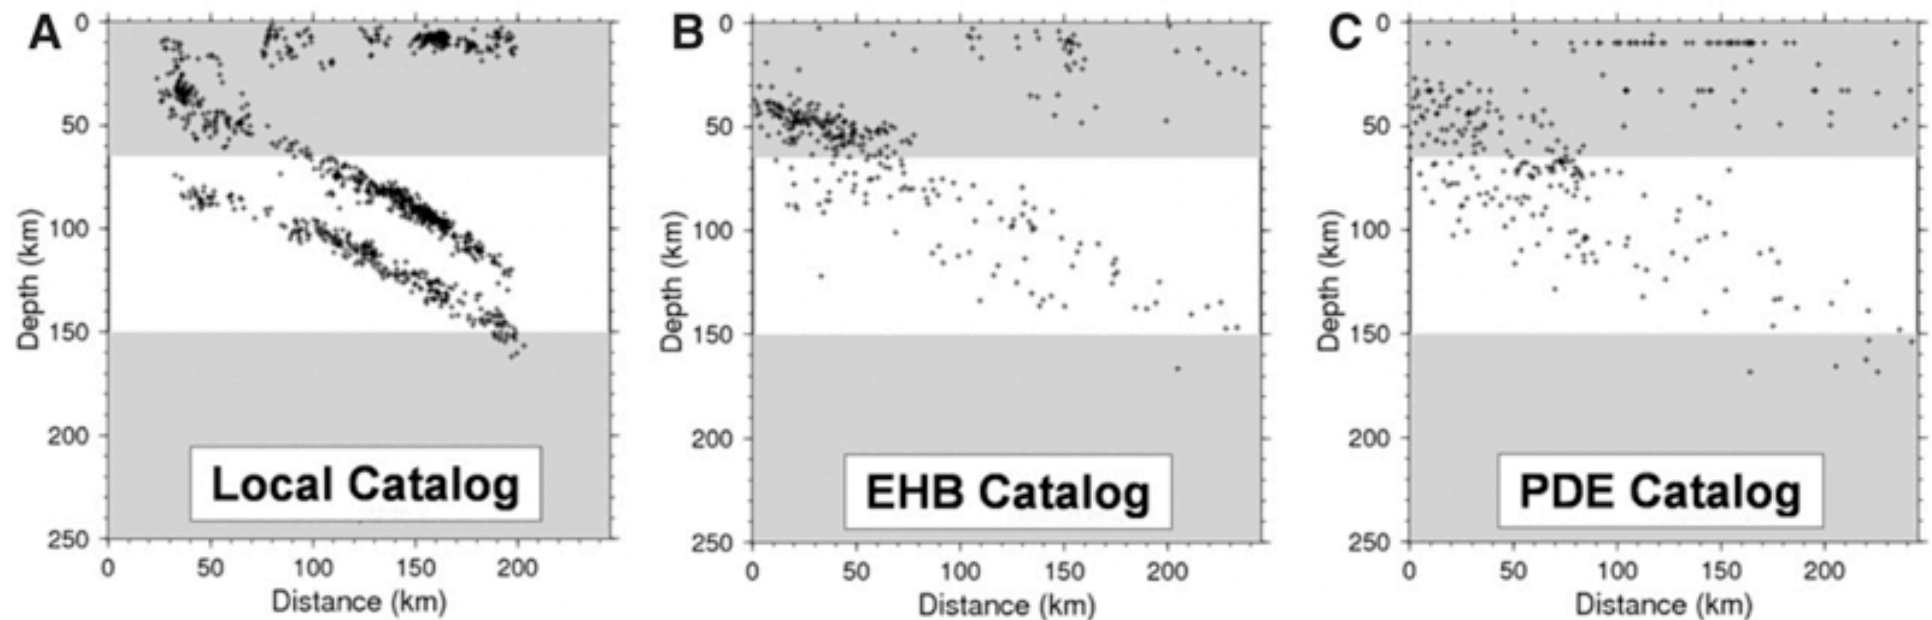

- > Juan de Fuca plate is young and hot, since it is created several 100's km off shore and is ~ 10Ma at trench
- > below 100 km, plate too hot to sustain brittle rupture

# JAPANESE SUBDUCTION ZONES

- > Japan has 2 separate subduction zones
- > Philippine plate is young, warm with shallow W-B seismicity like Cascadia
- > Pacific plate is old, cold, W-B seismicity to greater depths

# HYPOCENTERS IN NE JAPAN

- > note quality of locations with different networks
- > seismicity to at least 150 km
- > double seismic zone, both limbs due to H<sub>2</sub>O producing reactions

# SEISMICITY IN TONGA

- > hypocenters colour coded in depth
- > maximum depth of earthquakes to ~670 km
- > due again to mineral reactions

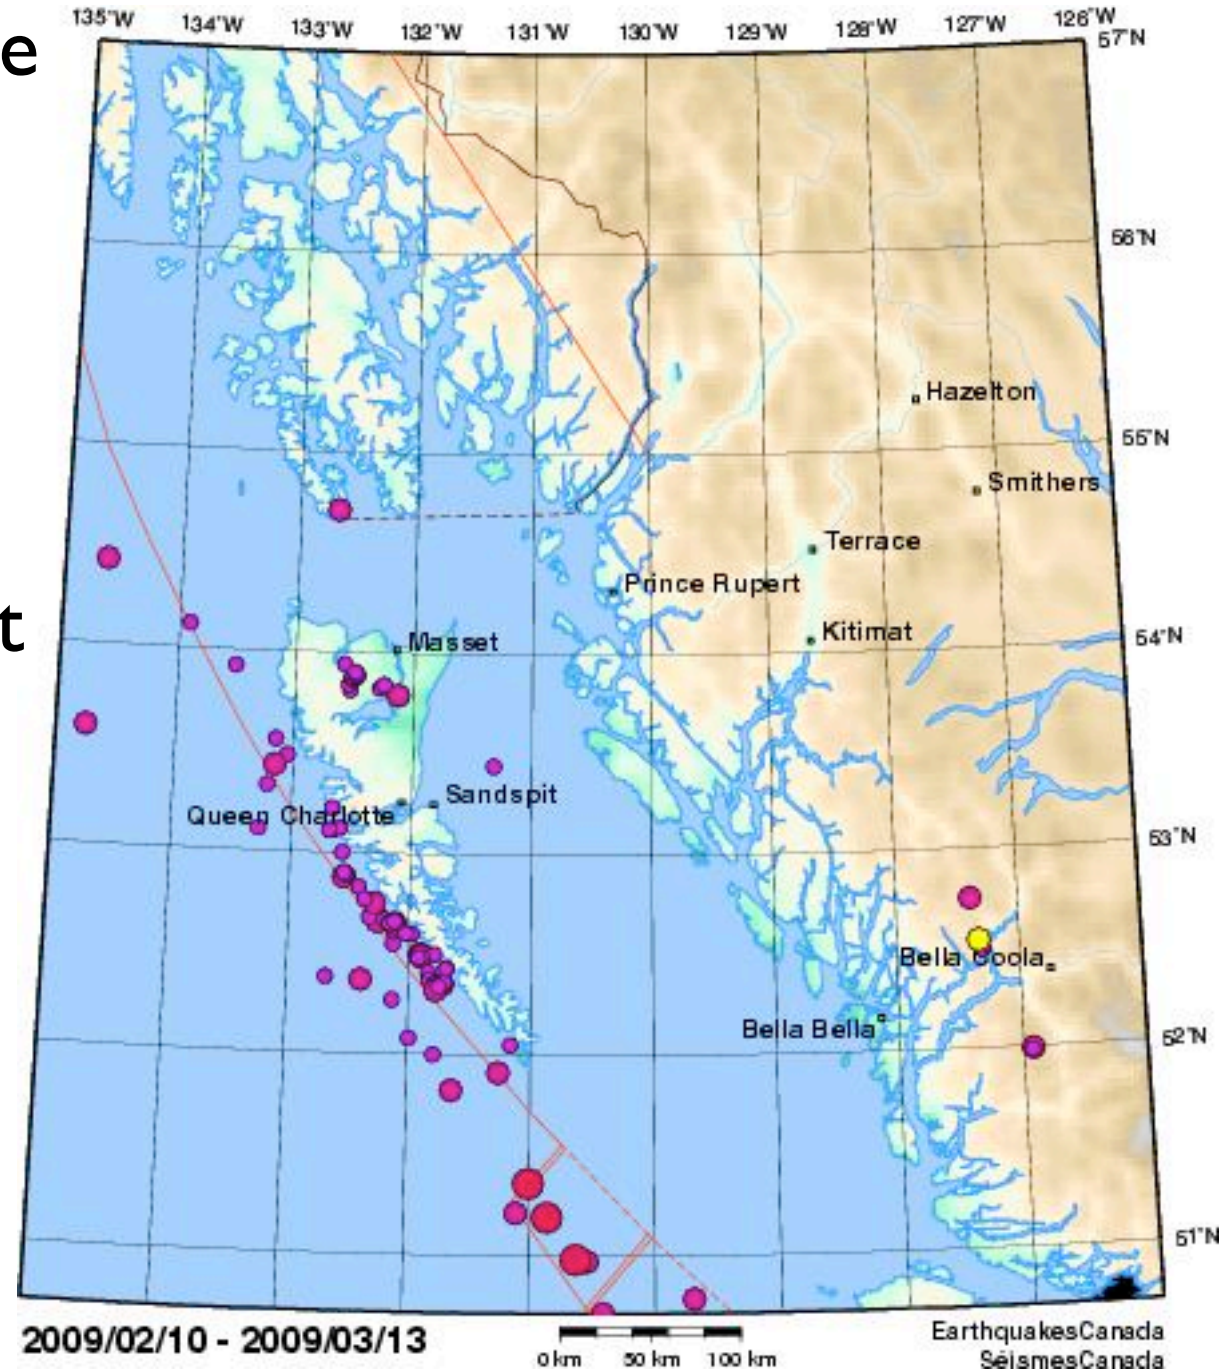

# RECENT QUAKES ON THE QUEEN CHARLOTTE FAULT

> Canada's version of the San Andreas

> major transform (strike-slip) fault

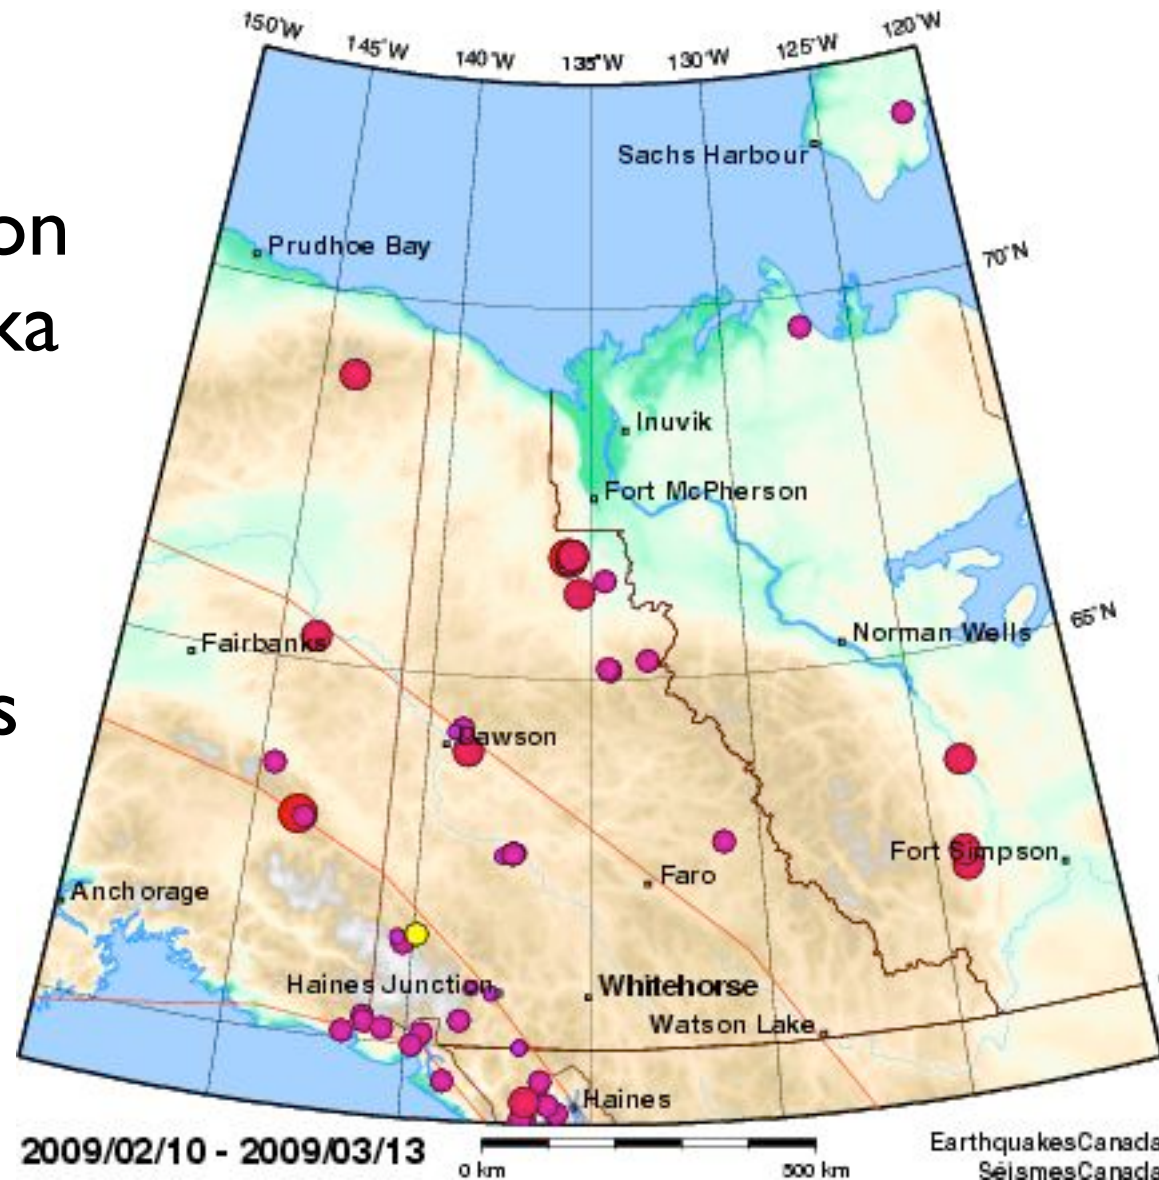

> site of Canada's largest historic quake (M=8.1, 1949)

# SEISMICITY IN NW CANADA

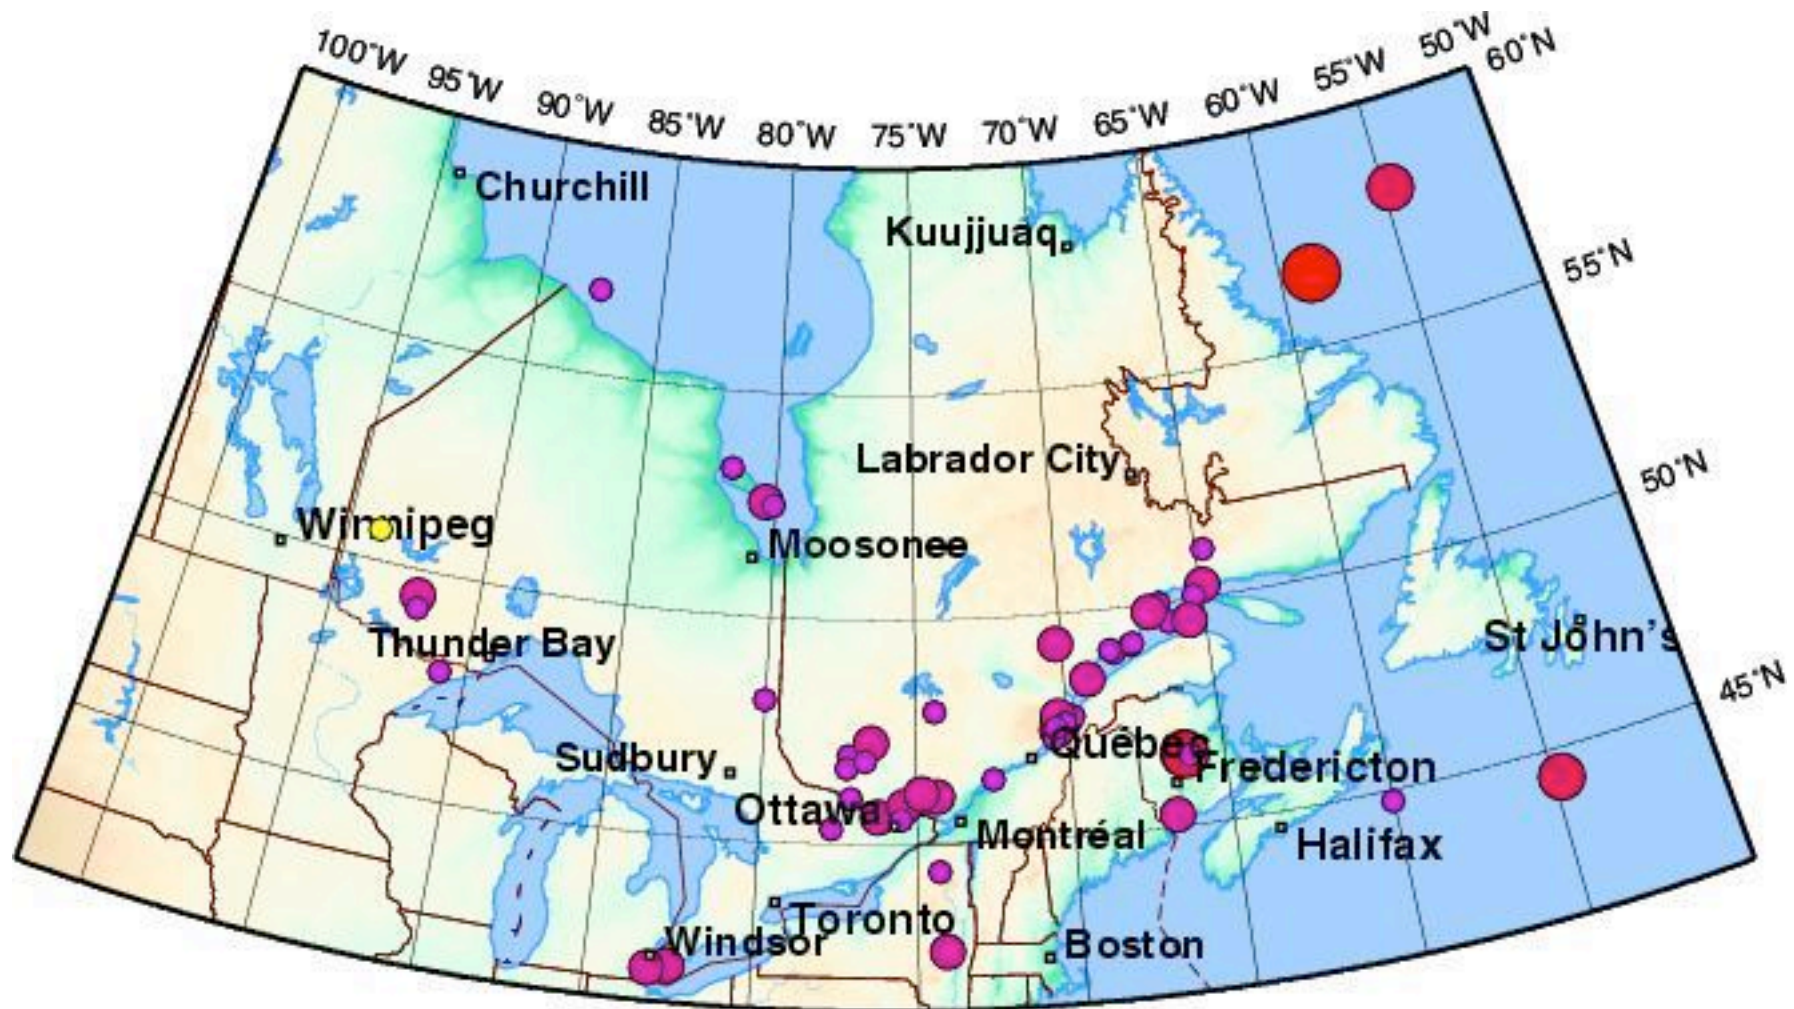

> Queen Charlotte Fault becomes Alaska subduction zone west of Yukon/Alaska border

> additional seismicity broadly distributed across Cordillera to Mackenzie Mtns

# EASTERN CANADA EARTHQUAKES

2009/02/27 - 2009/03/30

0 km 500 km 1000 km

Earthquakes Canada  
Séismes Canada

Recent earthquakes (most recent is shown in yellow)

● M < 2.0

● M ≥ 2.0

● M ≥ 3.0

● M ≥ 4.0

★ M ≥ 5.0

★ M ≥ 6.0

# EASTERN CANADA EARTHQUAKES

> Charlevoix region (near Quebec city) is most active zone in eastern Canada (5 eq's with  $M \geq 6$ )

> Ottawa-Bonnechere graben is another active region

> causes not well known, quakes appear to be located in zones of crustal weakness, perhaps related to ancient plate boundaries
